The bibenzyl skeleton is frequently found in natural products and other biologically active substances. Radical homocoupling provides a straightforward approach for the synthesis of bibenzyls in a single step, and the reductive homocoupling of benzyl halides has been vigorously developed. Contrasting to benzyl bromides and other designed precursors used in visible light-mediated homocoupling, benzyl chlorides are more abundant and chemically stable. However, chemoselective cleavage of the C-Cl bond remains challenging, and a small collection of studies has been reported so far. Herein, we report a catalytic reductive homocoupling of benzyl chlorides using zirconocene and photoredox catalysis. This cooperative catalytic system enables C-Cl bond cleavage of benzyl chlorides under mild conditions and facilitates the homocoupling of a broad array of benzyl chlorides, including the derivatives of pharmaceutical agents. The preliminary mechanistic investigations indicated the crucial role of hydrosilane in the catalytic cycle.
